

# Carbon Capture in the Southeast Asian Market Context

## *Sorting out the Myths and Realities in Cost-Sensitive Markets*

### Executive Summary

In recent years, Carbon Capture Utilization and Storage (CCUS) discussions have gained traction in Southeast Asia (SEA). CCUS' strategic value lies in its ability to retrofit existing assets and hard-to-abate sectors. The young fleet of coal and gas power plants in SEA suggests the region may present the right fit for CCUS applications.

It is critical to understand that CCUS is not a monolithic subject. Examples of CCUS applications include gas processing and power generation. Each application primarily runs on separate tracks with their own maturity and costs projections. Three applications currently dominate the discussions in SEA: gas processing, industries/product based CCUS for hydrogen/ammonia, and potential future usage in the power sector. Gas processing CCUS is arguably the lowest cost and most mature application, primarily due to the relative ease of capturing highly concentrated carbon dioxide (CO<sub>2</sub>) in its flue gas, compared to the diluted low-pressure CO<sub>2</sub> in power sector applications.

In planning ahead for their respective net zero targets, stakeholders in SEA should clearly understand what CCUS could and could not likely offer – sorting out the myths and realities. The Institute for Energy Economics and Financial Analysis' (IEEFA) summarises the following:

- **Discussions surrounding the need for 'policy support' should not veer from the big questions on CCUS: which CCUS drivers would be present in SEA countries? Carbon emissions valuations, strong public funding support or market drivers?** In IEEFA's view, very few of these drivers exist in SEA, other than Singapore. In a region where a carbon price is practically non-existent and the chance for it to reach more than US\$50/tCO<sub>2</sub> is unlikely in the near future, widespread CCUS use would likely be constrained. Several CCUS cost projections indicate that within the next several decades, the cost of CCUS in the power sector is unlikely to be competitive, particularly in light of the continual decline of renewable energy and storage costs. In 2020, the International Energy Agency (IEA) presented a CCUS cost projection under the Sustainable Development Scenario (SDS), which projects the decline in cost of CO<sub>2</sub> capture for coal power from circa US\$65/tCO<sub>2</sub> in 2020 to US\$40/tCO<sub>2</sub> in 2070 – a value likely far from the immediate reach of most SEA nations.
- **Three-quarters of the newly planned CCUS capacity in SEA is for gas**

**processing, a 'different' CCUS from the majority of other markets. Gas processing CCUS has been applied since the 1970s to deal with CO<sub>2</sub>-rich resources.** SEA is home to considerable gas resources which contain large amounts of excess CO<sub>2</sub> when produced. A combination of market drivers and the imperative to raise state revenue have been the most noticeable drivers to adopt CCUS. This CCUS is notably 'different' from other CCUS applications, as it captures the *excess* CO<sub>2</sub> from gas production, not the CO<sub>2</sub> from final use or combustion of the gas, which is more commonly done in other CCUS applications. In evaluating such projects, host countries need to understand the implications of the various CCUS investment drivers, such as the Internal Carbon Pricing (ICP) policies of investing companies. Through ICP, companies voluntarily embed a 'shadow' carbon price into their business decisions, which should have already moved the investors' baseline scenario. Finding a fair share of CCUS cost allocations between the host government and the investor remains crucial.

- **Representing CCUS as 'technologically mature' muddles public understanding as maturity means little when commercial applications remain far off.** A technology can be viable under the right circumstances – high carbon tax, large incentives, and tight emissions regulations – while remaining implausible in countries with no carbon pricing and lax emissions regulations. The United States (US) is home to half of the world's CCUS capacity, and their 45Q Internal Revenue Code currently applies US\$35-50 of tax credit for every tonne of CO<sub>2</sub> injected, with CCUS proponents proposing the incentives to be expanded to US\$85+/tCO<sub>2</sub>.
- **The power sector: with the high cost of failure involved and a patchy history, different pathways of scaling up CCUS should be expected compared to other, more nimble technologies such as solar PV and wind energy.** With the CCUS retrofit for a 240 megawatt (MW) coal plant costing US\$1bn in 2017, the cost of failure remains high. Government grants 'policy push' have and will likely continue to play a predominant role in influencing CCUS development. For instance, the US Government Accountability Office reported that the US government alone spent US\$1.1bn on demonstration projects between 2010 and 2017, with *none* of the eight government-supported coal CCS operational in 2022. The EU has spent at least €424m, with 'intended progress not achieved' as stated by the European Court of Auditors. Due to the high cost of failure, the design-build-prove cycle of CCUS will likely operate on a different time frame. Scaling up CCUS will likely play out differently compared to other technologies, which can make incremental improvements more readily.

Only one commercial power generation CCUS is operating globally at present. One for coal and none for gas. Claims of a continued cost decline trend have been largely based on feasibility studies instead of empirical evidence and should be evaluated with care. Boundary Dam CCUS in Canada received CAD240m in government funding, while Petra Nova, the only other plant, was shut down indefinitely in 2021 due to 'economic reasons' despite

having been supported by a massive US\$190m in funding from the US government.

- **CCUS is energy-intensive, and measuring the cost of CO<sub>2</sub> captured is insufficient, as the cost of CO<sub>2</sub> avoided needs to be the measure.** CCUS process consumes significant amounts of energy, of which associated emissions need to be considered. Current CCUS costs in power could easily add 6-9 c/kilowatt-hour (kWh) to the power generation costs. Further, in assessing the full CCUS cost in South East Asia, stakeholders will need to consider the predominance of subcritical coal plants, which generate higher emissions, and the generally lax emissions standards. The latter will potentially add to the cost as CCUS technology typically requires adequate flue gas pre-treatment standards.
- **The three potential leaders for CCUS in Asia are still inching slowly.** China's total CCUS capacity ranges between 2 to 4 Million Tonnes Per Annum (MTPA) CO<sub>2</sub> spread over dozens of small-scale facilities. South Korea's CCUS is largely limited to pilot projects, while Japan's CCUS long-term trial was built with 0.2 MTPA capacity. Compare this with US' Shute Creek plant with 7 MTPA capacity in a single plant. As the traditional leaders in energy technology and investments in the region – how these three countries move forward with CCUS will be important for SEA. It is especially important given the rapid decline of coal power in the US, home to most of the global capacity of CCUS, and potentially, along with it, its attention to coal power CCUS, a dominant part of the SEA power mix. It is notable that while Japan has some forms of regulatory-based emissions control, its carbon pricing remains paltry at best, with a carbon tax of US\$3/tCO<sub>2e</sub>, despite actively promoting CCUS in the SEA region.
- **Bilateral initiatives can be an ally for CCUS deployment in SEA, but the scale and cost intensity of CCUS make it unlikely to promote widespread adoption.** Initiatives such as the Joint Crediting Mechanism (JCM) initiated by Japan have listed more than 200 projects since 2013. The total emissions reduction is about 2.4 million total carbon dioxide (tCO<sub>2</sub>) per year, less than half the annual emission of a one-gigawatt (GW) coal plant. Such initiatives should be commended, but the role of CCUS will likely remain limited.

IEEFA believes that the establishment of CCUS in the South East Asian market within the next several decades will likely be limited around gas processing, and some industrial applications which could be supported by concessionary financings or bilateral initiatives.

CCUS in the power sector remains highly unlikely under the anticipated cost scenario projections. Even at US\$40/tCO<sub>2</sub> cost of capture, the effective total cost of \$50 to 60/tCO<sub>2</sub>, inclusive of transport and storage, will be beyond reach for most countries in the region. While the development of affordable coal power CCUS remains elusive, it is potentially even more so for gas power plants with its even more diluted CO<sub>2</sub> concentration.

The lack of supporting policy, legal, and regulatory framework is often touted as the primary barrier to CCUS applications. Sometimes, this is meant to ensure that CCUS adoption is recognized with supportive regulations. Most of the time, however, this statement alludes to the lack of a sufficient price attached to carbon emissions, and more specifically, that substantial public funding support is required for CCUS to take off.

The wave of enthusiasm of CCUS with the cluster concept, which combines multiple CO<sub>2</sub> sources to reduce cost and risks, should also be contextualized with the public funds attached to it. The UK government provided nearly £100m of funding, further backed by a £1bn CCUS fund to support its CCUS cluster plan, while the Norwegian government funded two-thirds of its planned US\$2.7bn CCUS cluster project. These public funds remain a necessity, despite both countries already exhibiting some of the highest carbon prices in the world. Enthusiasm for the cluster as a CCUS-enabler should remain grounded in the projections of CO<sub>2</sub> capture cost and the context of public funding availability.

**There is no dodging the big question: which CCUS drivers would be present in SEA countries?**  
*Carbon emission valuation, strong public funding support or market drivers?*

CCUS will undoubtedly remain an important consideration for some hard-to-abate sectors, such as steel and cement. It is nevertheless important for stakeholders to note the dynamics of the drivers behind them to evaluate the likely pathways in SEA.

Singapore remains an exception in the SEA region. The establishment of CCUS projects there remains plausible, given the concentrated industrial base, market drivers from export products and international companies, and more critically, the higher carbon pricing ambition.

SEA countries can use CCUS as a stepping stone to 'learn the ropes' of the technology and to anticipate future developments of carbon-capture based products and other applications. However, it should not distract from the adoption of other lower-cost and proven carbon abatement options in renewable energy and grid integrations, which should remain at the centre of SEA's attention toward decarbonization.

The recent Intergovernmental Panel on Climate Change (IPCC) report, released in April 2022, outlined the challenging costs of CCUS applications in the near future. With limited resources, CCUS is ultimately a question of priorities, as the costs will eventually land somewhere. It is also pertinent to ask whether the CCUS projects planned in the region match the 'intended CCUS' for each country's commitments toward their decarbonization goal.

It is possible that the power generation CCUS cost may decline substantially over the next two decades. However, the long history of its challenges and the factors outlined in this report suggests that this remains an open question, especially for adoption in cost-sensitive markets.

The CCUS train may eventually arrive, but before it does, it will likely need to make a lot of stops before eventually reaching the South East Asian shores. With the clock ticking toward the 2050 decarbonization timeline, SEA policymakers need to look closely at whether this is the right train to rely on.

## Background

Carbon capture, both for utilization and storage, gained substantial attention in recent years, with the rising urgency to mitigate CO<sub>2</sub> emissions. SEA recently noted an uptick in CCUS project plans and public discussions. With strong electricity demand growth and a relatively young coal and gas power plant fleet, the region is often touted as high potential for CCUS application.

The unique nature of CCUS, which can be retrofitted into hard-to-abate and existing assets, means it could play a substantial role in the net-zero pathways. Nevertheless, IEEFA has noted that the vastly diverse applications of CCUS across industrial and energy sectors often muddles the understanding, particularly for inexperienced stakeholders who may mistakenly think of CCUS as a single subject.

While several reports have evaluated CCUS through multiple angles, IEEFA considers it necessary to draw out the key facts for the public and policymakers to comprehend the evolving CCUS landscape and the diverging characteristics of CCUS applications – what it is and what it is not.

This report is the first of a two-part series covering the CCUS landscape of the South East Asian region. This report will focus on the preconditions of CCUS adoption, the predominance of gas processing CCUS in SEA, and the context of CCUS in power generation. The second part will be presented as part of IEEFA's evaluation of hydrogen and ammonia, which could be closely correlated to CCUS. Industrial applications, CO<sub>2</sub> utilization, direct air capture, and carbon storage potentials, are beyond the scope of this paper.

The term 'CCUS' is used as a general reference of carbon capture in this report for the purpose of simplicity. Specifically, Carbon Capture and Storage (CCS) refers to a process which captures carbon solely to be stored, while Carbon Capture and Utilization (CCU) uses the carbon, which at present, is primarily to produce more oil and gas.

This report is not intended to be exhaustive, nor as a 'deep dive' into CCUS technology options – but rather to provide a conceptual primer for the public, policymakers, and stakeholders to comprehend the ongoing development and context of CCUS in South East Asia.

### *A Very Brief Introduction to CCUS*

The global CCUS capacity currently stands at around 40 MTPA of CO<sub>2</sub> captured, with about half of the global capacity residing in the US.<sup>1</sup> This existing global capacity is comparable to about 7GW of coal power plant annual emissions. CCUS' strategic value lies in its ability to be retrofitted to existing power and industrial plants, applications in hard-to-abate sectors such as iron, steel, or chemicals, and for low-

---

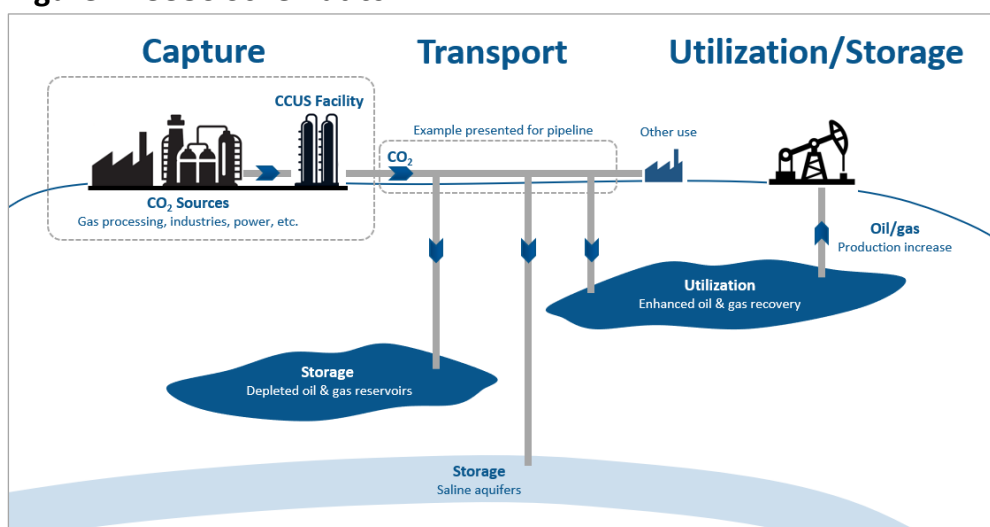

<sup>1</sup> Global Carbon Capture Storage Institute (GCCSI). [Global status of CCS 2021](#). 2021.

carbon hydrogen production.<sup>2</sup>

CCUS encompasses three distinct parts: capture, transport, and storage or utilization, as depicted in Figure 1 below. CO<sub>2</sub>, which is captured from various stationary sources such as gas processing, chemical process, and power generation plants, are transported to suitable sites, and stored or utilized, mainly underground. Often (in more than 60% of deployed CCUS facilities) these CO<sub>2</sub> are sold as a commodity to oil and gas companies that use it to enhance their production, hence the term: Enhanced Oil/Gas Recovery (EOR/EGR).<sup>3</sup> On other occasions, the CO<sub>2</sub> is permanently stored underground in saline aquifers or other underground deposits.

**Figure 1: CCUS Schematics**

CCUS terminology is evolving, and there are some terms and concepts that need to be clarified to contextualize and categorize different types of CCUS. Pre- and post-combustion capture describes at what stage the CO<sub>2</sub> is captured, whether before or after fuel is burned.<sup>4</sup> Other technologies are also in development, such as oxyfuel, which uses pure oxygen instead of air to increase CO<sub>2</sub> capture efficiency. Capturing CO<sub>2</sub> in higher concentrations is easier and cheaper than capturing it in more diluted forms commonly encountered in power plant exhaust gas.<sup>5</sup>

While various technologies have been applied in carbon capture, they are primarily a variation of solvent-based, physical-adsorption or membrane-based capture. New

<sup>2</sup> International Energy Agency (IEA). *IEA Energy technology perspectives 2020 – Special report on CCUS*. 2020.

<sup>3</sup> Global Carbon Capture Storage Institute (GCCSI). *Global status of CCS 2021*. 2021.

<sup>4</sup> Pre- and post-combustion are relatively new terminology attributed to the growing interest in capturing CO<sub>2</sub> from fossil fuels combustion. The chemical and gas industry has been capturing CO<sub>2</sub> for decades as part of their business process.

<sup>5</sup> The ease of capture is affected by a multitude of factors, primarily the concentration of CO<sub>2</sub> and the pressure of CO<sub>2</sub> the gas stream - the 'partial pressure'. For the benefit of non-technical readers, this paper will primarily refer to these factors as 'CO<sub>2</sub> concentration'.

designs, such as the Allam-cycle, are also undergoing development, although the nature of its design will likely not allow it to be retrofitted into existing assets.<sup>6</sup>

Amine solvent-based capture is arguably the most mature application for CO<sub>2</sub> capture. Its applications originated as early as the 1930s with various developments along the way to help mitigate its associated key challenges, energy penalty and degradations.<sup>7</sup> Energy penalty is associated with the energy required to use and reuse the solvent while degradation expresses the degrading of amine over time due to exposure to heat, O<sub>2</sub>, CO<sub>2</sub> and impurities such as NO<sub>x</sub> and SO<sub>x</sub>.<sup>8</sup> The latter impurities are prevalent in power plant flue gas, and are a crucial consideration for evaluating SEA CCUS application, which will be discussed further in the report.

There are fewer variations in the transport and storage stage of CCUS. In transportation, CO<sub>2</sub> is most commonly transported by CO<sub>2</sub> pipelines. 85% of all CO<sub>2</sub> pipelines reside in the US, although this constitutes only 0.2% of the US pipeline infrastructure.<sup>9</sup> CO<sub>2</sub> transportation by ship is currently in the nascent stage and is starting to be explored in the Norwegian Langskip project.<sup>10</sup> While applications of small-scale CO<sub>2</sub> shipping have existed for decades, several shipping industry giants have only recently begun to explore its wider applications.<sup>11</sup>

## *Drawing Distinctions Between the Variety of CCUS Applications*

As opposed to being a monolithic subject, CCUS is an aggregate of technology applications across varying sectors, each largely running in its own development tracks, drivers, and maturity level. While technology similarities may exist among different CCUS applications, they may involve different technicalities and approaches. Figure 2 illustrates the varying costs of CCUS applications, with the notable disparity between the lowest cost CCUS (gas processing) and the highest cost applications, from below US\$50 to greater than US\$130/tCO<sub>2</sub>.

Readers should be aware that CCUS interests vary significantly across regions with the diverse applications. The European Union (EU) is potentially focusing on CCUS for industries and hydrogen production, while ongoing CCUS discussions in SEA focus largely on three subjects: gas processing, products -hydrogen/ammonia production, and potential future use in the power sector.

Ideally, CCUS should be prioritized toward hard-to-abate sectors such as cement, petrochemicals, iron, and steel. The inherent production processes within these industries and the limited alternatives means that CCUS is likely needed. However, within the South East Asian context, the considerable cost-impact of CCUS on the product price would likely raise the barrier of entry for such applications.

The general characteristics of each category are outlined in Table 1 below. The list is not exhaustive but rather provides a wider view of ongoing plans in South East Asia.

**Table 1: Three Distinct CCUS Tracks in South East Asia**

CCUS Category	Technology Maturity	Cost of CCUS <sup>12</sup>	Potential Dominant Parties Involved in SEA
<p><b>Gas Processing</b></p> <p>Capture of CO<sub>2</sub> associated with excess CO<sub>2</sub> content (impurities) in gas production, particularly salient for gas reserves with high CO<sub>2</sub> content</p>	Mature. Has been applied since the 1970s to meet required gas specifications	Low	<p><b>Host governments, private/state-owned entities</b></p> <p>Gas production with royalty/revenue share between the host government and oil and gas operator. Cost of CCUS will likely be borne by both parties with end-product sold at market or regulated price. The portion of cost allocations potentially determined by inherent leverages and policies of each party.</p> <p>Example: Gas production CCUS</p>
<p><b>Products: Hydrogen/Ammonia Production</b></p> <p>Capture of CO<sub>2</sub> associated with industrial process</p>	Cost reduction required to improve product competitiveness	Medium to high	<p><b>Private/state-owned entities</b> – owner of plants. Cost of CCUS passed through to customers with low-carbon products sold at a premium price.</p> <p>Example: ‘Blue’ hydrogen or ammonia production<sup>13</sup></p>
<p><b>Power Plants (coal and gas)</b></p> <p>Capture of CO<sub>2</sub> associated with fuel combustion</p>	<p>Low to medium, commercially challenging.</p> <p>Technical challenges remain prominent in existing projects</p>	<p>High to very high</p> <p>Low CO<sub>2</sub> concentration from flue gas 12-15% (coal)</p> <p>Very low for gas 4% (gas combined cycle)<sup>14</sup></p>	<p><b>Private/state-owned entities</b> – owner of power plants</p> <p><b>Host government</b> – as applicable</p> <p>Costs (inclusive of energy penalty costs) passed through to consumers or host governments depending on the power market structure.</p> <p>Example: Power plants operating under Power Purchase Agreements with/without take-or-pay clause</p>

## Which CCUS Drivers Would Be Present in SEA?

With its high associated costs, both in capital investment and ongoing operations, CCUS essentially represents a ‘tax’ to continue emitting carbon. Someone in the value chain *will* need to internalize the costs. Ultimately, that added cost will fall to either consumers – in the form of higher tariffs or taxpayers – due to the need for

<sup>12</sup> Estimates for Hydrogen is based on Steam Methane Reforming (SMR) process International Energy Agency. [CCUS in clean energy transitions](#). Page 101, 2020.

<sup>13</sup> ‘Blue’ products is a term commonly attributed to products which are produced from fossil fuels equipped with CCUS to remove emissions while ‘green’ products are produced using renewable energy.

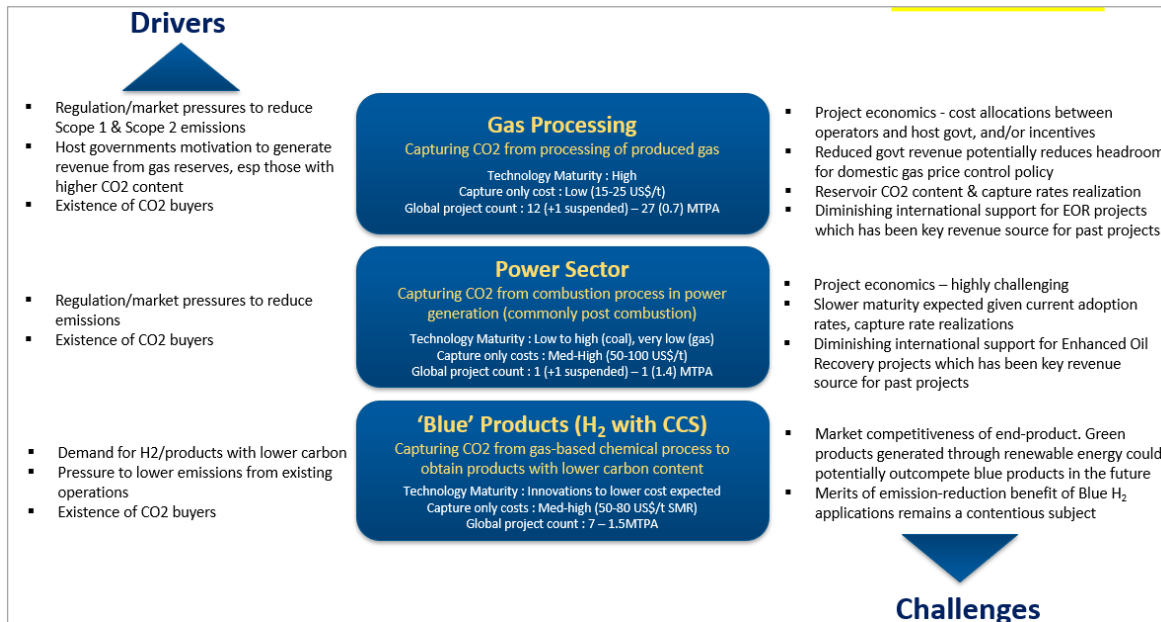

<sup>14</sup> National Energy Technology Lab - US Department of Energy. [Post combustion CO<sub>2</sub> capture](#). Accessed 20 January 2022.

government to fund subsidies or credits.

Therefore, attaching a high value to the carbon emissions is necessary for CCUS projects to proceed – whether through a carbon tax and credit market, premium low-carbon product prices, or other policy-based incentives. The United States’ CCUS establishments were supported by the availability of CO<sub>2</sub> pipeline and CO<sub>2</sub> demand for EOR, but most notably, through generous tax credit incentives and government funding.

Figure 3 outlines the drivers and challenges for CCUS applications. Each category exhibits vastly different market behaviours and technical/cost characteristics, which will dictate their potential pathways in the region. Some lower-cost CCUS applications with strong drivers will likely take off first, but may not necessarily correlate with the likelihood of other CCUS applications.

**Figure 3: Diverging Characteristics of SEA Potential CCUS Uses**

Globally, the lack of supporting policy, legal, and regulatory frameworks is often touted as the primary barrier of CCUS applications. Sometimes, what this simply means is that supportive regulations should recognize CCUS. Most of the time, however, this statement alludes to a lack of sufficient price attached to carbon emissions, and more specifically, that substantial public funding support will likely be required for CCUS to take off.

### Attaching a High Cost to Carbon Emissions

The United States’ Section 45Q Tax Credit currently applies US\$35 to 50 of tax credit

for every tonne of CO<sub>2</sub> captured.<sup>15</sup> The Norwegian Sleipner project has also been established under a strong carbon tax regime, in which by injecting CO<sub>2</sub> the project avoided NOK one million per day in Norwegian CO<sub>2</sub> taxes.<sup>16</sup> Under such conditions, corporations are encouraged to implement CCUS, whether to avoid penalties or gain incremental income.

Table 2 outlines the current state of the carbon pricing mechanism and the ongoing CCUS plans in the SEA region.

**Table 2: South East Asia CCUS and the Carbon Pricing Landscape**

Sources: Compiled, World Bank, International Carbon Action Partnership (ICAP), ASEAN.

In terms of a carbon price as a key driver for CCUS, Singapore is the leader in SEA with a carbon tax of US\$ 3.7 set until 2023. The current level still pales in comparison to the carbon price in the EU which hovered more than US\$60/tCO<sub>2</sub>e in recent years, the generous incentives in the US, or even China's emissions trading scheme price which ranges from US\$6.5 to 9.7 since it was launched.<sup>24</sup>

In February 2022, Singapore's Finance Minister outlined an aggressive carbon tax hike, rising to US\$18/tCO<sub>2</sub>e by 2024, and potentially reaching a value between US\$37 and 60/tCO<sub>2</sub>e by 2030.<sup>25</sup> This meaningful action will further single out Singapore as the leader in SEA carbon pricing, but one which will need to be placed in the context of other SEA countries' emission scales, carbon pricings, and their GDP per capita, as outlined in Table 2 and Figure 4.

Source: *Our World in Data, World Bank.*

With carbon pricing virtually non-existent in most SEA countries, a second CCUS driver will likely dominate in the region – the need to monetize CO<sub>2</sub>-rich gas resources.

The dynamics of gas processing CCUS are different from most other CCUS applications, as gas production could be correlated with an urgency to raise state revenue. The value attached to the emission is internalized within the costs – i.e. reduced project revenue – borne by the gas producers and host countries. In the South East Asian market context, this second driver will likely play an important role for earlier CCUS deployment, as we will see in later sections. Table 3 outlines the existing CCUS plans in the region.

**Table 3: South East Asia CCUS Project Plans**

Project	CCU/S Type	Country	Production Status	Operating entity	Avg Annual CCU/S capacity (MTPA CO <sub>2</sub> )	Remarks	Reported CCUS commencement plan
Kasawari	Gas processing	Malaysia	New development	Petronas	3.7	FEED contract awarded, expected completed before end of 2022. Kasawari gas field expected on stream by 2023, with CCS onstream by 2025, capacity estimates varies from 3.7-4 MTPA. Malaysia aim to create storage hubs for the region.	2025
Tangguh	Gas processing (EGR)	Indonesia	Tangguh field is in production with expansion plan	BP	2.5	FEED preparation. BP has announced plan of development approval from the Indonesian authority SKK Migas. Current emission estimates 5 MTPA CO <sub>2</sub> which will increase to 8 MTPA CO <sub>2</sub> with additional LNG Train in absence of CCUS	2026
Gundih	Gas processing (EGR)	Indonesia	In production	Pertamina	0.3	Pre-FEED study, Pertamina supported by various parties & Japan METI. Potential support from Japan JCM.	2024/5
Sukowati	Gas processing (EOR)	Indonesia	In production	Pertamina	0.6	Ongoing studies, Pertamina, Lemigas, Japex, supported by Japan METI. CO <sub>2</sub> source 30km away from the target oilfield	2030
Sakakemang	Gas processing	Indonesia	New development	Repsol	2	Under discussion	2027
Banggai-Sulawesi Ammonia	Industry - Ammonia production	Indonesia	In production	Panca Amara Utama	1	Pre-feasibility studies expected completion by mid 2022. Plan to produce 700,000 tonne of clean ammonia annually for export to Japan coal power plants.	TBC
Singapore Hub	Potential focus on industries / products	Singapore	N/A	TBC	2	Potentially focused on industries or lower-emission products. In absence of potential storage sites cooperation with other country storage may be considered. There has also been mentions of plans to explore gas power CCUS.	2030

Source: Compiled.

It should be acknowledged that an explicit valuation of emissions is not the sole determinant of emissions mitigation actions, as other policies and regulations can play an important role.<sup>26</sup> Indeed, improvements have been noted through regulations such as low carbon/clean fuel standards and other legal emissions standards worldwide.<sup>27</sup> However, within the SEA context, there has been limited regulations relating to carbon emissions mitigation, and the future outlook of such regulations remain an open question for the foreseeable future.

In evaluating the likelihood of CCUS adoption, stakeholders are well advised to begin by looking at what drivers will likely be present within a particular market. Most of the time, such drivers may come directly from the state and regulatory domain, but at other times, they may originate from the private sector.

### *Public Funding Support – Past, Present and Future*

Government grants' 'policy push' has played a dominant role in pushing CCUS developments in the past decade. The US government alone has spent US\$1.1 bn on

<sup>26</sup> Cullenward, D & Victor, D. Making climate policy work. 2020.

<sup>27</sup> Regulation implementation varies from pure regulatory control to encourage lower emissions to a combination of emission credit issuance/market implementation.

demonstration projects between 2010 and 2017, with at least €424m spent by the EU.<sup>28</sup>

In 2021, the United States Government Accountability Office (GAO) highlighted the ‘high-risk selection’ of the CCUS projects funded, especially those in the coal power sector. Table 4 outlines some of the findings. Despite the massive public funding, most coal power projects encountered economic issues with only one coal power project, Petra Nova, ever reaching operational stage. The plant later ceased to operate in 2020 due to economic challenges after only three years in operation. Two of the three industrial projects remained in operation and involved the production of hydrogen and ethanol, a lower-cost CCUS application, compared to power generation.

**Table 4: US GAO CCUS Public Funding Report Findings**

CCS Project	Projects Selected	Project in Operation (2020)	US Department of Energy Funding
Coal Project	8	0	US\$ 684 million
Industrial project	3	2	US\$ 438 million

Plans to attach CCUS to the Integrated Gasification Combined Cycle (IGCC) power plant, which involves gasification of the fuel before being combusted, have also failed to take off. The discussion on IGCC CCUS is outside the scope of this paper, but it is worth noting that its pinnacle IGCC demonstration project in the US, the Kemper

<sup>28</sup> US Government Accountability Office. [CCS: Actions needed to improve DOE management of demonstration projects – Report to congressional committees](#). December 2021.

Project, encountered severe problems. The plant was initially touted as a model for the rise of ‘clean coal’ projects, utilizing lignite coal. Its costs ballooned from an estimated US\$3 bn to US\$7.5 bn and were later suspended. The US Department of Energy provided more than US\$400m of public funding for the project.<sup>29</sup>

**A note on the CCUS cluster.** In recent years, the revival of global attention on CCUS has been bolstered by the concept of ‘CCUS cluster/hub’ where the CCUS Transportation and Storage (T&S) plans are based on aggregating multiple CO<sub>2</sub> sources. Clusters are expected to help T&S investors manage their investment risks, rather than rely on a single CO<sub>2</sub> source model.

**Table 5: Select CCUS Cluster Plans**

Project Hub/Cluster	Stated Objectives	Funding and Supports
<b>UK East Coast Cluster (ECC, combining Teesside and Humber) and HyNet North West</b>	ECC target of 27 MTPA of CO <sub>2</sub> emission by 2030 – capturing nearly 50% of all UK industrial cluster CO <sub>2</sub> emissions. <sup>30</sup> HyNet 10 MTPA by 2030. Both projects outlined plans for hydrogen production in addition to CCUS.	HyNet supported by <b>£33m</b> from UK Research and Innovation (UKRI). UKRI also reported funding awards of <b>£62m</b> between Humber and Teesside project. <sup>31</sup>  Potentially to be supported by the UK government <b>£1bn Carbon Capture and Storage Infrastructure Fund (CIF)</b>
<b>Norway Longship (Langskip)</b>	Capture 1.5 MTPA CO <sub>2</sub> by 2024, combining emissions from cement factory, ammonia plant, and waste incineration facility. Further expansion plans are outlined for 5 MTPA.	Norwegian government will be supporting around <b>US\$1.8bn</b> (NOK 16.8bn) out of the total project cost of US\$2.7bn (NOK 25.1bn), about two-thirds of the entire cost. <sup>32</sup>
<b>United States Houston CCUS cluster</b>	Target of 50 MTPA CO <sub>2</sub> . Involving 14 companies primarily from industrial applications. <sup>33</sup>	Limited details, ExxonMobil has disclosed the need for “collective support of industry and government, with a combined estimated investment of \$100 billion or more” <sup>34</sup>

It is notable that despite the new model, the residual investment risks remain significant, and that government support will be crucial. Table 5 outlines some of the most notable CCUS cluster establishment plans, and the significant government backing behind it. Currently, there are limited details on how the Houston CCUS will progress.

The United Kingdom (UK) government clearly stated that part of the motives for their involvement in CCUS cluster developments was first to overcome the coordination failure of private investments, where it is unlikely for private players to coordinate investments for transport and storage of an appropriate size. Secondly, to overcome the first mover disadvantage, earlier developers will likely have to pay higher costs than latecomers.<sup>35</sup>

**The prominent role of governments in backstopping CCUS developments remain crucial and unlikely to be afforded by most SEA countries.**

In South East Asia, Singapore has envisioned establishing a carbon capture hub, targeting 2MTPA of CO<sub>2</sub> capture capacity by 2030.<sup>36</sup> As home to major refineries and petrochemical complexes, nearly half of Singapore's emissions are concentrated in industrial areas such as Jurong and Bukom. While both Shell and Exxon are exploring the potential of CCUS, an Exxon representative highlighted concerns that in the Asia Pacific, "the value of carbon is relatively low; therefore, it doesn't attract public and private investments."<sup>37</sup>

Enthusiasm in establishing clusters do not negate the fundamental question of potential CCUS drivers in the SEA region. It is also important to note that CCUS applications for many sectors, such as power, are dominated by the *capture costs*, not the latter part of transporting and storing the CO<sub>2</sub>. The cluster concept could potentially bring a CCUS project through the last mile, but highly unlikely when there is no solid foundation for it to be built upon.

The high failure rate for CCUS projects is a reminder of the high risks involved in CCUS demonstration projects. The prominent role of governments in backstopping CCUS developments, either through policy intervention or other incentives remains crucial. It is also something which is unlikely to be afforded by most SEA countries. It should also be expected that with a large amount of public money invested, *if and when*, the supported technologies come to fruition, their earlier adoptions will

## Market Drivers: Corporations, Internal Carbon Pricing and CO<sub>2</sub> Buyer's Market

International corporations are increasingly under pressure from investors and governments to disclose the effects of their business activities on the climate crisis. These are most commonly presented in the different emission 'scopes' emitted by a company.

At a very broad level, corporations are pressured from both their demand side, the buyers of their products, and the investors.

In 2021, the corporate world saw the establishment of a new International Sustainability Standards Board (ISSB) to develop 'a comprehensive global baseline of high-quality sustainability disclosure standards', a major milestone that exemplifies the growing inertia of corporate scrutiny.<sup>38</sup>

To assess and mitigate future carbon-related risks, a growing number of companies use the Internal Carbon Price (ICP) to incorporate the cost of emissions in their business plans. One common practice is to apply the carbon price as a 'shadow' theoretical price in their decision-making process or applied as a fee to entities within the companies based on their respective emissions.<sup>39</sup>

Setting aside the variations in methodology to set the ICP, and that ICPs most commonly only consider Scope 1 and Scope 2 emissions; the involvement of major international companies reflects the trend that carbon-related risks assessments are gaining traction and will likely escalate in the future. Table 6 below illustrates a non-exhaustive list of ICP implementations on

### Scope 1, 2 and 3 Emissions

A company's emission is categorized into three different scopes, as outlined by the Green House Gas (GHG) Protocol Corporate Standard.

**Scope 1** emissions from sources owned or controlled by the company.

**Scope 2** represents indirect emissions from purchased energy inputs such as electricity or heat which are not generated directly by the company.

**Scope 3** represents all emissions in the value chain, including those located in the upstream (input) and downstream (output) part of the company's process.

Specific for companies involved in energy *extraction*, it is important to note that the end product emissions (Scope 3) constitute a much greater portion of the overall. Below chart and Figure 6 further illustrates the typical emission scopes for oil and gas companies.

ICP is not the sole mechanism for corporations to encourage low-carbon investments. It is nevertheless frequently used to translate ‘commitments’ into more tangible value for their organizations. Moreover, ICP allows companies to transparently display to the public how they incorporate carbon-related future risks in shaping their business decisions.

ICP policies can move ‘the goal posts’ for corporate investment decisions. Hence, host countries of CCUS projects would be well-served to understand investors’ ICP policies to enable a mutual understanding of each party’s starting points.

**Who will buy the CO<sub>2</sub>?** CCUS involves substantial costs and corporations naturally look for ways to recoup them. A key enabler for past CCUS projects has been to sell the CO<sub>2</sub> as a by-product to external buyers or to use them internally. On both accounts, EOR/EGR applications dominate the landscape. When sold externally, CO<sub>2</sub> provided the revenue stream needed to get past the commercial barriers. Internally, they are commonly used to gain increases in oil and gas production.

It is worth noting that when the CO<sub>2</sub> is used for EOR/EGR, the project will inevitably be exposed typical commodity price cycles. As exemplified in many projects – in times of low oil price, or when competition with other energy sources intensifies, the economics of CCUS projects will likely be affected.

While these models could potentially prevail in some portions of future CCUS plans, including in SEA, it is also increasingly under scrutiny from the international community. While the primary reason for the public to support CCUS through funding and policies is to reduce emissions from fossil fuels, EOR/EGR travels in the opposite direction to facilitate an increase in oil and gas productions.

A policy paper issued by the Asian Development Bank (ADB) in 2021 noted specific exclusions for supporting and financing CCUS associated with EOR.<sup>53</sup> This reinforces the trend that support of CCUS to acquire concessionary funding and international support will likely be targeted to specific applications, with CCUS related to hydrocarbon extraction likely to continue under scrutiny in the future.

In addition to the state and corporate drivers, when domestic drivers may not be sufficient to support CCUS, international support may present the next best alternatives to increase the value of carbon emissions.

### *External Drivers: Valuing Emissions Through International Agreements and Supports*

**Bilateral agreements.** In the absence of a strong regulation or high carbon valuations in domestic SEA markets, bilateral agreements have been noted in cases such as the 0.3 MTPA CO<sub>2</sub> Gundih project in Indonesia, which aims to be supported

---

<sup>53</sup> Asian Development Bank. [New ADB Energy Policy to Support Energy Access and Low-Carbon Transition in Asia and Pacific](#). 20 October 2021.

Asian Development Bank. [Energy Policy: Supporting Low-Carbon Transition in Asia and the Pacific](#). September 2021.

by the Joint Crediting Mechanism (JCM) as the first SEA CCUS demonstration project.<sup>54</sup>

JCM is a bilateral agreement initiated in 2013 between Japan and partner countries to develop carbon mitigation projects in developing countries. A combination of concessionary funding, grants and technology support from Japan is given in exchange for recognizing a portion of the realized emission reductions to satisfy Japan's emission reduction target.<sup>55</sup>

**International carbon credits.** In addition to bilateral initiatives, international trading of carbon credits provides another potential avenue. While the recent United Nations Conference of the Parties 26 (COP26) provided a new footing, its historical implementation has seen a fair number of challenges, as exemplified in the Clean Development Mechanism (CDM) initiative under the Kyoto Protocol.<sup>56</sup> Taking lessons from past challenges, project environmental integrity, loopholes, and supply-demand balance in the international carbon market will undoubtedly be on the priority watch list for international stakeholders.

Among this myriad of international support avenues, bilateral agreements such as the JCM, could be the most likely ally for CCUS establishment in SEA. Nevertheless, the prospect for large-scale deployment of CCUS under such a scheme will likely be limited, given the scale of the current JCM scheme. As of December 2021, 205 JCM projects have been listed since 2013, with a total expected GHG emission reduction of 2.4 MTPA CO<sub>2</sub> – less than half the annual emissions of a 1GW coal power plant.<sup>57</sup>

Establishing such programs is commendable as it has been a key enabler of many emissions-reduction projects. Nevertheless, considering Japan's raised JCM ambitions, the capital-intensive nature of CCUS means that the role of such a scheme as the backbone of a widespread CCUS adoption in SEA remains an open question.<sup>58</sup>

## SEA CCUS Plans Are Dominated by Gas Processing CCUS, a 'Different' Kind of CCUS

More than 60% of the current CCUS capacity deployed globally is applied for gas processing. With three quarters of SEA's CCUS plans geared for gas processing, the recent uptick in SEA's CCUS discussions is largely a form of catching up on this past trend (Figure 5 and 6), CCUS for gas processing mainly serves to separate the excess 'reservoir-associated CO<sub>2</sub>' from the useful components of the gas. It has been

<sup>54</sup> J-Power. [Commencement of feasibility study for the first SEA CCS demonstration project](#). 19 July 2021.

<sup>55</sup> JCM. [Basic concept of the JCM](#). Accessed on 2 February 2022.

<sup>56</sup> CDM allows emission-reduction activities in developing countries to earn certified emission reduction credits (CER) which can be traded, sold, and used by industrialized countries to meet their emissions target under the Kyoto protocol.

UNFCCC. [UNFCCC website](#). Accessed on 2 February 2022.

<sup>57</sup> Global Environment Centre Foundation. [List of projects under JCM financing programme by MOEJ](#). 2021.

<sup>58</sup> The Energy Conservation Centre - Japan. [Ministry of Environment to raise the JCM target](#). 13 July 2021.

adopted since the 1970s and is arguably one of the lowest-cost and most mature variety of CCUS applications.

As gas is produced, impurities such as CO<sub>2</sub> could be present in the gas stream at varying proportions. They will need to be separated to meet required specifications before the gas is distributed and utilized. Consumers have little use of the CO<sub>2</sub> content, which can also complicate various processes in transporting the gas in the value chain. CO<sub>2</sub> content is commonly required to be below the 2-4% range for pipeline transport and end use, with a much more stringent limit of 0.005% CO<sub>2</sub> (50 parts per million volume, ppmv) prior to being liquefied into LNG.<sup>59</sup>

**With three-quarters of South East Asia's CCUS plans geared for gas processing, the recent uptick in these CCUS discussions is largely a form of catching up on this past trend.**

**Figure 5: SEA CCUS Is Dominated by Gas Processing**

Source: IEEFA, ASEAN, IEA.

The separation of excessive CO<sub>2</sub> from the gas stream is therefore a necessary step in processing marketable gas, regardless of the final destination of the separated CO<sub>2</sub>. Gas producers voluntarily embed the process and its costs as part of its revenue-generating activities. In the absence of tight emissions regulations, the captured excess CO<sub>2</sub> are often vented into the atmosphere. In other cases, the gas producers look for ways to use or sell the CO<sub>2</sub>, primarily for EOR/EGR. Lastly, the CO<sub>2</sub> is stored permanently underground to a lesser extent.

<sup>59</sup> International Gas Union. *Guidebook to gas interchangeability and gas quality* page 64-65. 2011. API. *LNG Operations – Consistent Methodology for estimating GHG emissions*. 2015. KBR. *Natural gas specification challenges in the LNG industry*. 2012.

In certain parts of the world, the excess CO<sub>2</sub> within the gas reservoir can become a prohibitive factor in commercializing the gas. Higher CO<sub>2</sub> content, particularly in the range of 15% to 80% can significantly impact the commerciality and environmental viability of these 'CO<sub>2</sub>-rich' resources – this consideration, as we will later see, plays an important role for CCUS in SEA.<sup>60</sup> The challenges primarily lie in two aspects, the need to handle large amounts of CO<sub>2</sub> and the lower volume of useful fuel in gas production, which raises the unit cost of gas production.

**Figure 6: Gas Processing Dominates Deployed CCUS Capacity**

Source: IEA, *CCUS facilities in operation by application, 1980-2021*.

### *A Different CCUS: Gas Processing CCUS Is Covering a Different Emission Scope Compared to Other CCUS*

As gas processing CCUS is mainly about 'capturing excess CO<sub>2</sub>', CCUS in gas processing is not about reducing Scope 3 emissions due to the final combustion/use of gas, but rather to minimize production-related Scope 1 emissions from gas with excessive CO<sub>2</sub> content. This contrasts with other CCUS applications in the industrial and power sector, which aims to minimize the emissions coming from the *end consumption* of fossil fuels, whether by combustion or as feedstock materials.

The touting of gas as a 'clean fuel' with an emissions advantage over coal diminishes when the gas production is accompanied by the venting of millions of tonnes of CO<sub>2</sub> into the atmosphere. In gas production, emissions also come from other processes besides those captured excess CO<sub>2</sub>, such as the liquefaction process in LNG plants.

To put the scale into perspective, in the absence of CCUS, Australia's Barossa LNG

<sup>60</sup> Burgers et.al. *Worldwide development potential for sour gas*. 2011.

project (16-18% CO<sub>2</sub>) will, from its production and venting activities, potentially emit more CO<sub>2</sub> compared to the amount of LNG produced.<sup>61</sup>

The necessity of CCUS is further exemplified in Australia's Gorgon LNG project. With 14% CO<sub>2</sub> reservoir content, the plant would emit more than four million tonnes of CO<sub>2</sub> annually. A A\$3.1bn CCS facility was deployed as part of the government project sanctioning requirements.<sup>62</sup>

The Gorgon CCS project has failed to deliver, underperforming its self-set targets for the first five years by around 50%. To offset its target, Gorgon has recently agreed to acquire and surrender credible greenhouse gas (GHG) offsets recognised by the Western Australian government. The shortfall amounts to 5.23 million tonnes of CO<sub>2</sub>, with cost estimates varying from US\$100 million to US\$184 million. A report made public by the Australian government in 2022 further outlined that the CCS plant injected 2.26m tonnes of CO<sub>2</sub> over a one-year period, significantly below its targeted 4 MTPA capacity.<sup>63</sup>

**CCUS in gas processing is *not* about reducing Scope 3 emissions resulting from the final combustion/use of gas, but rather to minimize production-related Scope 1 emissions from gas with excessive CO<sub>2</sub> content.**

### *A Quick Look at the Global Gas Processing CCUS Landscape*

CCUS for gas processing has been around since the 1970s, with the most notable plants in Sleipner (Norway) and LaBarge (US). In the latter, CO<sub>2</sub> comprised up to 65% of the gas produced from the reservoir.<sup>64</sup>

The higher CO<sub>2</sub> concentration and partial pressure in gas processing emissions

---

<sup>61</sup> IEEFA. Santos' Barossa gas field emissions create major risks for shareholders. 2021.

<sup>62</sup> Gorgon CCS is based on at least 80% capture and storage requirement from the reservoir CO<sub>2</sub> and has been supported by A\$60m of Australian federal government funds. It is also notable that the CCS project only started in 2019 while the first LNG shipment commenced in 2016. Sydney Morning Herald. Chevron's five years of Gorgon carbon storage failure could cost \$230 million. 11 November 2021.

allows for a lower cost of capture compared to other CO<sub>2</sub> emissions.<sup>65</sup> While the cost of capture is fairly low at below US\$30/tCO<sub>2</sub>, the cost for transport and storage can vary widely from US\$10 to more than \$40/tCO<sub>2</sub> and can be the dominant determinant in CCUS implementation.

**Figure 7: Global Landscape of Gas Processing CCUS**

Source: Compiled, see Appendix A for details. CCUS facility size is influenced by the level of CO<sub>2</sub> and the volume of gas production.

Emissions associated with gas processing directly impact the highly visible Scope 1 & 2 emissions, and companies bound by emissions reduction commitments will tread carefully. A single gas processing plant in CO<sub>2</sub>-rich resources could easily emit more than 3 MTPA CO<sub>2</sub>, a figure that would cause notable emissions' rise in even the largest oil and gas companies (Figure 8). CCUS has, therefore, increasingly become imperative in developing CO<sub>2</sub>-rich resources.

<sup>65</sup> Partial pressure expresses the pressure of CO<sub>2</sub> in the gas stream, which, in tandem with CO<sub>2</sub> concentration plays a large role on determining the ease of carbon capture process.

## SEA Gas and CCUS: The Rush to the Door

LNG has historically been a critical enabler for South East Asian gas to reach the east Asian consumer markets. However, SEA has been facing a steady decline in its LNG exports in recent years (Figure 9). With maturing gas fields and persistent under-investments, countries such as Malaysia and Indonesia now must grapple with more challenging gas assets, some of which contain high levels of CO<sub>2</sub> impurities.<sup>66</sup> With international companies, financing, and gas consumers involved, CCUS is now becoming an imperative.

In August 2021, INPEX, which operates Indonesia's undeveloped Masela gas field, announced a potential delay in the project's development and slated the potential need for CCS or CCUS.<sup>67</sup> This tendency is mirrored in the company's recent announcement for CCUS deployment in Australia, with capacity planned up to 7MTPA.<sup>68</sup> CCUS potential developments have also been reported in Petronas Kasawari, BP Tangguh, and Repsol Sakakemang, all located in Malaysia and Indonesia.

Globally, the concentration of underdeveloped gas fields with high CO<sub>2</sub> content appears to be concentrated in South East Asia and Australia (Figure 10).<sup>69</sup> From the

<sup>66</sup> In certain countries this is further coupled with increasing focus to use gas for domestic demand, as observed in Indonesia.

<sup>67</sup> Reuters. [Inpex to delay investment decision on Indonesia's Abadi LNG project due to pandemic, climate change](#). 10 August 2021

<sup>68</sup> Nikkei. [Japan's Inpex to spearhead carbon capture at Australian gas field](#). 9 February 2022.

<sup>69</sup> Changes to developments of these resources may have taken place since 2009, however the map outlines the general landscape of CO<sub>2</sub>-rich gas reserves.

Burgers et al. [Worldwide development potential for sour gas](#). 2011.

potential list of gas processing CCUS projects planned globally, nearly half of the capacity is located in the South East Asian region.<sup>70</sup> While many of these projects are still in the early development stages, this trend likely reflects the push to develop gas fields with higher CO<sub>2</sub> content as soon as possible, anticipating potential changes in market attitude.

**Figure 9: South East Asia Declining LNG Exports and Outlook**

Source: *S&P Global Platts Analytics*. LNG exports from Malaysia, Indonesia and Brunei. 2021 onwards are estimates.

Equipping CO<sub>2</sub>-rich gas resources with CCUS does not necessarily bring a premium price. The prime objective is to reduce emissions to compete with other gas resources with less reservoir CO<sub>2</sub>. With the LNG value chain already embedded with higher emissions than pipeline transport, the stake is even higher for LNG-based project development.

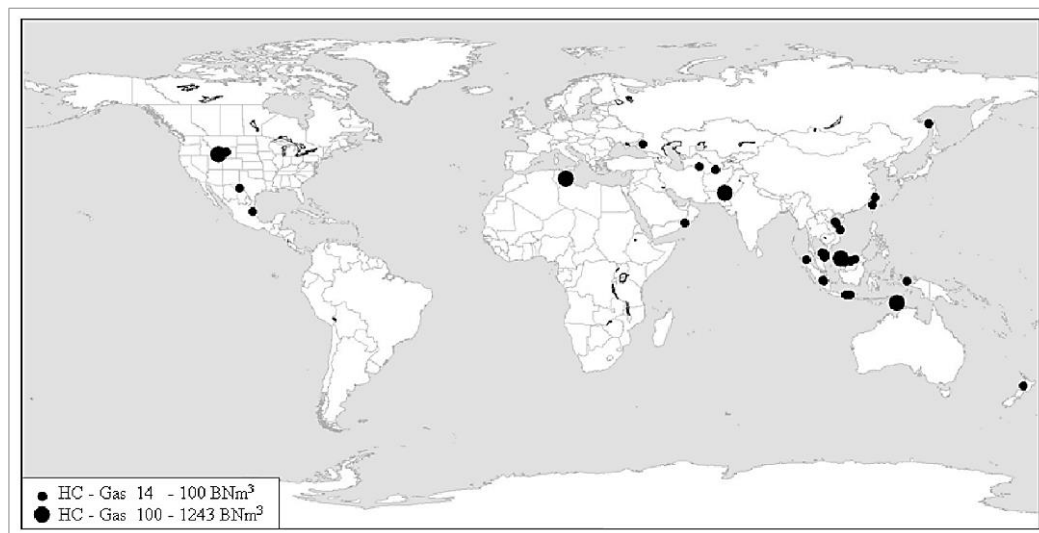

In recent years, several long-term LNG sales purchase agreements (SPAs) have been signed between Singapore's Pavilion Energy, Qatar Petroleum and Chevron, which mandated the reporting of emissions for each LNG cargo. 2021 saw the establishment of the Carbon Neutral LNG Buyers Alliance in Japan comprised of 15 companies with notable leadership from Tokyo Gas.<sup>71</sup>

<sup>70</sup> Based on IEEFA market estimates. Indonesian Government approval for BP Tangguh Vorwata CCS plan of development was reported on August 2021. Global CCS Institute. *Global status of CCS 2021*. 2021.

**Figure 10: Indicative Map of Undeveloped and Underdeveloped CO<sub>2</sub>-rich (15-80%) Oil and Gas Fields**

Source: WFJ Burgers, et.al., IHS.

LNG trade accounts for a sizeable portion of cross-border gas trades. Given the rising rates of imports led by countries such as China and India, the CO<sub>2</sub> content of LNG supply sources will become a highly material consideration. Couple these factors with net zero pledges in importer countries, such as European countries and Japan. These trends likely indicate that disclosure of associated emissions of LNG cargoes and competition to lower emissions will continue to intensify.

In the future, host countries with CO<sub>2</sub>-rich gas reserves will likely be persuaded further by oil and gas companies to accommodate the use of CCUS. Given that CO<sub>2</sub> removal is an integral part of gas production, it is imperative that host governments clearly understand the baseline investment scenario without CCUS, and other influencing factors such as the ICP, to comprehensively evaluate cost allocations and to avoid the public bearing more than the fair share.

The additional cost of CCUS would also be particularly salient for countries with domestic gas price control policies. CCUS costs would reduce the state revenue opportunity, which could be used as a hedge against price fluctuations and would likely lower the headroom to maintain price control.

## Power Sector – Different Pathways for CCUS Cost Decline

People often confuse CCUS as ‘a mature technology in need of policy support’, while at other times as ‘a technology in great need of innovation to lower the cost’. These confusions likely arise due to the diverse CCUS applications, each with distinct characteristics and maturity. Therefore, it is worthwhile to revisit the discussion surrounding its application maturity and particularly to flesh out the two measures

of readiness – technical and commercial readiness.

### *Power Generation CCUS Is a Different Game Altogether – Energy Penalties, Application Maturity and Cost Projections*

Power plants inherently emit large volumes of CO<sub>2</sub>. A 1GW coal plant could emit 5 to 7 million tonnes of CO<sub>2</sub> annually.<sup>72</sup> Combined cycle gas power plant would emit less CO<sub>2</sub>, but the lower concentration of CO<sub>2</sub> in its exhaust gas means that the capture cost would likely be higher.

South East Asian countries have been more conservative in forecasting the role of CCUS in their mid-term power sector projections, as observed in various national planning documents. Malaysia's Tenaga Nasional Berhad and Indonesia's PLN have expressed longer-term interest in exploring the subject, with PLN stating the potential use of CCUS post-2035, after the technology is commercially mature.<sup>73</sup>

Countries such as Vietnam have limited disclosure of their expectation of CCUS for the power sector, while Singapore appears to be more inclined to explore CCUS for industrial applications.<sup>74</sup> Cost-sensitive markets, especially those with rigid power purchase agreements, are bound to be more cautious in implementing CCUS, given its renowned commercial challenges.

It is interesting to note that Indonesia has listed CCUS in its long-term low-carbon strategy document submitted to the United Nations Framework Convention on Climate Change (UNFCCC). The country stipulated that by 2050, the role of coal power will remain significant, with a scenario outlining that '76% of the coal power plants are equipped with CCS to achieve zero emissions in coal power plants'.<sup>75</sup>

### *Current State of Power Generation CCUS*

Globally, there is only one operating power generation CCUS, located in Boundary Dam, Canada. A second CCUS plant, Petra Nova in the US, was operational between 2017 and 2020. It was later reported to be 'shut down indefinitely', at only four years old.<sup>76</sup>

<sup>76</sup> Reuters. [Problems plagued US CO2 capture project before shutdown: document](#). 7 August 2020.

Both coal and gas power are prevalent in SEA. The average age of existing coal power plants in SEA is 11 years (coal power plants' average lifespan is 30 to 40 years), and CCUS offers a potential lifeline to be retrofitted into existing power plants.<sup>77</sup> However, the pertinent questions pertain to the projection of its application maturity and the rate at which its cost can be driven down.

CCUS for the power sector is more costly and complex due to the diluted CO<sub>2</sub> in the flue gas stream, as evidenced in the string of historical issues in retrofitting CCUS into power plants. In contrast to gas processing and certain chemical processes, which could generate exhaust gas in relatively high CO<sub>2</sub> concentrations, coal plants' exhaust gas typically contains 12-14% of CO<sub>2</sub> while gas turbine power plants generate 3-4% CO<sub>2</sub>.<sup>78</sup> Small in concentration, but large in terms of absolute volume globally.

It is worth noting that CCUS is an inherent part of revenue-generating activities to produce marketable gas in gas processing. In power generation, in the absence of strong drivers, such as a high carbon price or massive subsidies, CCUS could be seen solely as costs that will be passed on to someone, whether to corporations, the government, or the ratepayers.

Over the years, IEEFA has published a comprehensive body of knowledge in assessing the economics and viability of CCUS projects, particularly in the North American region. Table 7 outlines the two CCUS power generations projects, which came into operation, both supported by generous government grants.

It is also important to note that while the development of affordable coal power CCUS remains elusive, the development of gas power CCUS is potentially even more challenging given the more diluted CO<sub>2</sub> concentrations (~3-4%) compared to coal plants (12-14%).

It is generally expected that as more CCUS projects in the power sector develop, lessons learned will reduce the cost over time. While the timeframe of such progress remains an open question, SEA policymakers should remain aware of the following key subjects in evaluating and planning for power generation CCUS.

## Who Will Pay for the Energy to Run CCUS?

Capturing CO<sub>2</sub> consumes a large amount of energy, which effectively reduces the amount of electricity that can be delivered to consumers.<sup>88</sup> Under regular operations, power plants already consume a portion of the power they generate for self-consumption. CCUS imposes additional energy penalties into the mix, typically by drawing steam or power to operate the capture process.

CCUS could consume up to 20% to 30% of the power generated by the plant, with an expected net efficiency reduction of 6 to 12 percentage points.<sup>89</sup> Decades of technological progress have been devoted to increasing coal power plant efficiency by a mere 7%, from the sub-38% of subcritical plants to the ~45% of Ultra Super Critical (USC) plants.<sup>90</sup> Therefore, a loss of 6 to 12% due to increased self-consumption poses a substantial barrier for many CCUS applications.

Based on per-tonnage captured CO<sub>2</sub> basis, current CCUS costs in coal power could easily add 6 to 9 cent/kWh to the power generation costs. Proper assessment should also consider

### CO<sub>2</sub> Capture Rates

As reducing emissions is the main goal of CCUS, CO<sub>2</sub> capture rates is a subject of great importance. Capture rates describe the amount of CO<sub>2</sub>, described in percentage, which can be captured by CCUS from a process, while the remaining emissions are released into the atmosphere.

Globally, capture rates of 85 to 90% is commonly planned. A study by IEAGHG in 2019 suggests that increasing the capture rate from 90% to 99%+ can be achieved with a modest increase in LCOE (7%) and CO<sub>2</sub> avoided costs (3-8%).

These, however, will need to be evaluated against historical realizations. Experiences in projects such as Petra Nova and Gorgon CCUS have all noted challenges in meeting the CO<sub>2</sub> capture targets for various reasons. Researchers at MIT have also noted the rising incremental costs and diminishing returns to achieve higher capture rates.

Petra Nova's actual capture rate averaged 70% from 2017 to 2019, when including the emission from its gas-powered turbine for CCS, the capture rates go down to 58%. Boundary Dam capture rates between October 2014 and December 2021 was 53%. Both projects had promised a 90% capture target.

<sup>88</sup> Energy consumption can be in the form of drawing steam from the power plant to heat solvent-based CCUS process.

<sup>89</sup> Conservative reduction figures presented. Reductions in output should also incorporate any additional flue gas pre-treatment installations required to accommodate CCUS (see later sections).

Increase in fuel consumption ranges from 24-40% (supercritical coal) and 11-22% (gas), 6 to 9% efficiency reduction on gas and ultra supercritical coal plants, based on *new* plants with 90% capture rate. Existing reports indicated greater efficiency loss in CCUS retrofits.

ASEAN Centre for Energy. [ASEAN CO<sub>2</sub> Emissions from Coal-Fired Power Plants: A Baseline Study](#). 2021.

the impact of emissions generated by the CCUS energy consumption.

To compete in a competitive electricity market, the high cost of CCUS will need to be compensated either by selling the captured CO<sub>2</sub>, receipt of government incentives or by charging a premium price to the consumers.

In markets with rigid long-term take-or-pay Power Purchase Agreements (PPA), it is likely that power plant owners expect the utility company, state-owned or private, to pay the full cost of the power generation capacity. In contrast, in competitive markets, the additional cost of CCUS will need to compete head-on with other lower-cost power generation options. For CCUS, that question then becomes – would a consumer pay a premium for CCUS-generated electricity, or would they rather save money by buying from a lower-cost source, such as renewable energy.

Furthermore, in subsidized power markets where there is less chance of increasing electricity prices, the government will likely in the end, bear the full costs of CCUS implementation, with monies sourced from allocations of the national budget. The question for government then becomes, do we allocate a budget for buying CO<sub>2</sub> or do we use that money for investment in cheaper sources of energy or higher priority items?

### *The Road to Low-Cost CCUS Will Likely Be Plagued With Many Giant Project Casualties*

With only one operational power generation CCUS, determining technological maturity could prove challenging. The Global Carbon Capture Institute (GCCSI) has listed nine power generation CCUS projects in the ‘advanced development’ stage, with an additional two under construction. IEEFA’s evaluation of the project list concludes with the following:

- All the projects in the advanced development stage have received various government grants ranging from US\$2.8m to \$21m, primarily in supporting feasibility studies and Front-End Engineering and Design (FEED).
- Capture capacities vary widely, from 0.12 to 6 MTPA CO<sub>2</sub>.
- Nine out of eleven projects plan to retrofit CCUS into existing power plants.
- At least seven different technology provider companies are involved with a variation of amine-based carbon capture dominating the technology class.
- The United States government has been the most dominant public funder, trailed behind by the United Kingdom and Australia.
- Two projects have announced delays in 2021, San Juan and Project Tundra. Both projects outlined the intention to acquire low-interest loans or loan guarantees from the US government to fund the projects.

The complete list of power generation CCUS evaluated is enclosed in Appendix B.

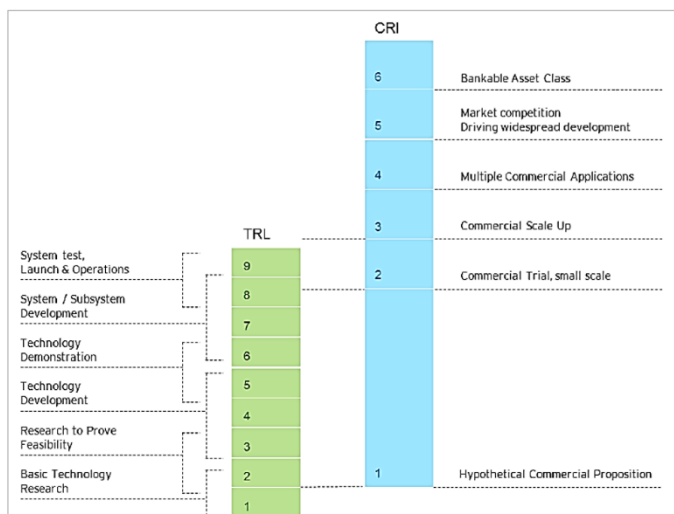

In comprehending technological maturity, indicators that can assist include the 1-to-9 scale of the Technology Readiness Level (TRL).<sup>91</sup> A report by GCCSI<sup>92</sup> in 2021 provided a comprehensive list of the various Research & Development (R&D) stages of CCUS technologies and their respective TRLs. In understanding such a concept, however, readers should naturally also incorporate economic and market-related aspects in projecting their potential deployment pathways. Just because a technology solution is feasible, it does not necessarily mean that it is cost-effective compared to alternatives.

The process of technological innovation is inherently associated with uncertainties surrounding the technology's capabilities, limitations, and development trajectory.<sup>93</sup> Nevertheless, stakeholders would be well advised to envisage under what market circumstances such technology would likely thrive, if and when, they scale up.

Frameworks such as the Commercial Readiness Index (CRI) developed by the Australian Renewable Energy Agency (ARENA) could help evaluate the potential commercial readiness of technology as they reach higher TRL levels (Figure 11).<sup>94</sup> While it has its limitations, such a framework would be useful to provide a more comprehensive view.

**Figure 11: Commercial Readiness Index (CRI) and Technology Readiness Level (TRL)**

Source: Australian Renewable Energy Agency.

<sup>91</sup> Technology readiness levels (TRLs) was initially developed at NASA in the 1970s and was later adopted by various institutions such as the European Commission as a tool to evaluate maturity of a technology. Level 1 indicates initial conception with level 9 being fully in service.

<sup>92</sup> Global CCS Institute (GCCSI). [Technology Readiness and Costs of CCS](#). 29 March 2021

<sup>93</sup> European Commission Directorate general for research and innovation. [Technology readiness level: guidance principles for RE technology](#). 2017.

<sup>94</sup> Australian Renewable Energy Agency. [Commercial Readiness Index for renewable energy sectors](#). 2014.

IEA-RETD. [Commercial readiness index assessment](#). 2017.

The commercial readiness of a technology could further vary based on the regulatory context of its application. A technology may be commercially viable when placed under a certain operational context, such as a high carbon price environment with a strict emissions regulation. The same technology could be far from ready in more cost-sensitive markets with lax emissions regulations.

Stakeholders should note the following points in evaluating the development of CCUS for the power sector, as well as its wider applications.

- **First mover disadvantage – when technology demonstrations typically cost greater than \$200M+.** With a large amount of investment required to build CCUS at scale, earlier adopters could be disadvantaged. There will undoubtedly be many projects with challenging economics on the road towards commercial CCUS scale-up. When a medium scale 240MW power plant CCUS retrofit costs US\$1bn, the stake is undoubtedly high. While public funding support has seen an increasing trend to support CCUS and CCUS hub development, it remains to be seen whether they will be able to sufficiently entice innovations and spur project developments to drive down the cost fast enough for adoption in emerging markets.
- **Potentially limited future growth potential and useful lifetime in power generation – as the competition continues to drive down cost.** As the cost of renewable and energy storage technology declines, conventional power generation will likely continue to be outcompeted by the cheaper renewable energy power. Battery costs have declined by 97% since 1991.<sup>95</sup> Even with CCUS costs declining in the coming decades, CCUS will face fierce competition. As the current power plant fleets age, coupled with limited new build of coal power plants, uncertainty will likely arise on the useful lifetime of CCUS in the power sector. Furthermore, stakeholders should note that CCUS plant operations largely relies on fossil fuels, exposing it to the typical commodity price cycles, in contrast to the zero marginal costs of renewable energy. These factors, taken together, could have a

**On the road towards the commercial scale-up of CCUS, there will be many projects with challenging economics. When a medium-scale 240MW power plant CCUS retrofit costs US\$1bn, the stake is certainly high.**

<sup>95</sup> MIT News. [Study reveals plunge in lithium-ion battery costs](#). 23 March 2021.

detrimental effect on the potential investment landscape.

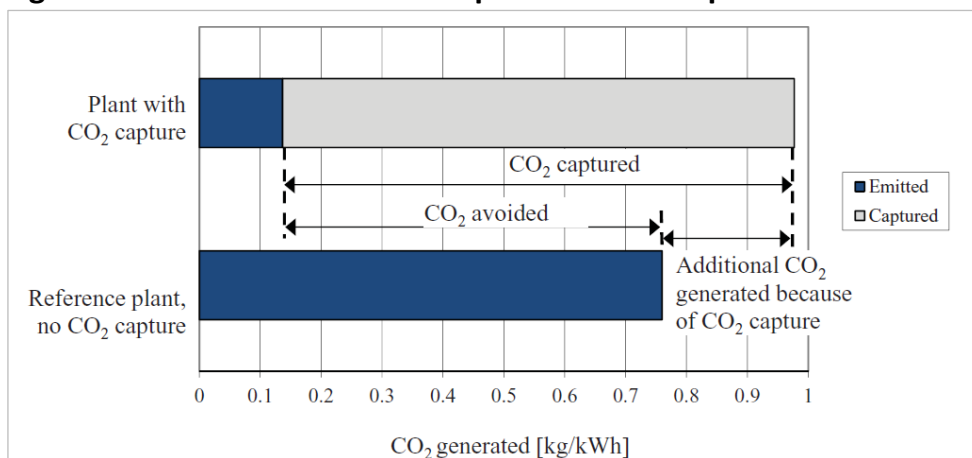

- **Stakeholders should be mindful of past power generation CCUS which stopped short at FEED or pre-FEED stage and are mostly cancelled – nearly fifteen plants with 28 MTPA CO<sub>2</sub> total capacity.**<sup>96</sup> Most of the projects have not seen further developments due to various reasons, largely around economics, lack of established CO<sub>2</sub> buyers and carbon credit markets/incentives. Many of these projects were initially planned to be supported by massive government funding, as exemplified in the initial plan for Longannet (UK, £1bn), Mountaineer (US, US\$334m), and Pioneer CCUS projects (Canada, CAD779m). Comprehensive evaluation of these projects could shed more light on the key barriers and the future outlook of power generation CCUS, while paying close attention to the cost and type of technology involved.
- **Cost of CO<sub>2</sub> captured is insufficient – the cost of CO<sub>2</sub> avoided should be the main measure.** The ultimate goal of CCUS will need to be associated with how much CO<sub>2</sub> is being avoided, and not solely captured. The emissions coming from the energy intensive CCUS process will need to be considered in the assessment. While this is a well-known concept for industry insiders, uninitiated unaccustomed stakeholders should also be familiar with the critical difference between the two terms, as illustrated in Figure 12 below. Cost of CO<sub>2</sub> avoided will inherently be higher, as the cost of CCUS will be spread over a smaller amount of CO<sub>2</sub> volume. Readers should also note that the majority of current CCUS facilities employ *planned* capture rates of 85% to 90%. While noting that reaching such planned capture rates has proven challenging in a number of projects, even at such level the process will still leave out considerable CO<sub>2</sub> emissions. Raising the capture bar at 98% – 99% and higher should become the norm.<sup>97</sup>

---

<sup>96</sup> IEAGHG. [Toward zero emissions CCS in power plants using higher capture rates or biomass](#). 2019

<sup>97</sup> IEA GHG report suggested that increasing capture rates from 90% to 99% increase cost by only 4 to 10% in power generation, for chemical absorption based CCUS.

IEAGHG. [Towards zero emissions CCS in power plants using higher capture rates or biomass](#). 2019.

**Figure 12: CO<sub>2</sub> Avoided vs CO<sub>2</sub> Captured for Example Gas Power**

Source: Mathieu, P. & Bolland, O., IPCC.<sup>98</sup>

- Lessons from Petra Nova and Boundary Dam 3 should be placed in the open, disclosing actual costs and operational information.** For a more transparent assessment of past power generation CCUS, it is imperative that associated parties are willing to place the lessons learned from these two power plants in the open. This is especially important after the ‘indefinite shutdown’ of Petra Nova after only four years in operation, despite being scaffolded by massive US government funding.
- Readiness of adequate flue (exhaust) gas pre-treatment in existing power plants.** CCUS deployment will likely require considerable exhaust gas pre-treatment prior to the CO<sub>2</sub> capture process. Large amounts of pollutants such as NO<sub>x</sub> and SO<sub>2</sub> in the flue gas, will potentially decrease the performance of typical CCUS operations.<sup>99</sup> While pre-treatment equipment is more common in developed countries, a specific assessment of the regulatory and market context in individual SEA countries will be needed. It should be noted that flue gas will also be affected by the power plant characteristics and fuel compositions. Predominance of subcritical coal assets which generates emissions and the use of lower-grade coal would also need to be part of the assessment. In absence of an adequate level of existing flue gas pre-treatment equipment, the costs of pre-treatment equipment retrofit, and its associated energy cost will need to be added to the CCUS cost planning. It can be generally concluded that lax pollution control/air quality standards would likely be a major impediment for CCUS development.
- Increase in water usage with CCUS deployment** also needs to be considered. CCUS deployment can increase in cooling water usage up to 50%

<sup>98</sup> Mathieu, P. & Bolland, O. Energy Procedia. Comparison of costs for natural gas power generation with CO<sub>2</sub> capture. 2013.

<sup>99</sup> IPCC. Carbon dioxide capture and storage. 2005.

World Bank. CCS for Coal-fired Power Plants in Indonesia page 32. 2015.

more, with water withdrawal increase ranging from 25 to 200% higher has been reported. Proper technical and environmental impact assessments will be necessary to mitigate such risks, including incorporating potential associated costs.<sup>100</sup>

IEEFA acknowledges that there are potential strategic roles for CCUS in the path towards a net zero world. Nevertheless, the implementation of CCUS in the power sector in South East Asia is deemed less likely, given the potentially slow trajectory of the carbon pricing regime in the region. When power generation CCUS does become commercially mature, earlier adoption is expected in less cost-sensitive parts of the world.

### Cost Projections

A recent report from the Asia Investor Group on Climate Change (AIGCC)<sup>101</sup> incorporated multiple CCUS scenario outlooks developed by Wood Mackenzie in several countries. The projections incorporate a top-down evaluation of the 2040 scenario with current country policies (Energy Transition Outlook) and an aggressive decarbonization scenario with an elevated carbon tax (Accelerated Energy Transition 2). Under such scenarios, both coal power+CCS and gas power+CCS will still be significantly more expensive than solar+storage in China, India, and South Korea, although coal and gas could still be competitive in Japan under the current policy scenario.<sup>102</sup>

**Figure 13: IEA Projection of CCUS Capture Costs Under the IEA Sustainable Development Scenario**

Source: *CCUS in clean energy transitions*. IEA. 2020.

<sup>100</sup> IPCC. *Climate Change 2022 – Mitigation of Climate Change* page 6-39, 6-75. Accessed 11 April 2022.

<sup>101</sup> AIGCC. *Investors should scrutinise Asian CCS plans as new analysis finds large-scaled deployment could fall short*. Accessed 11 April 2022.

<sup>102</sup> Note that Wood Mackenzie's scenarios provides a top-down/indicative trend evaluation and not a comprehensive case-specific economic evaluation of CCUS.

AIGCC. *CCS in the decisive decade for decarbonization – The case for Asia*. 2021.

Separately, the IEA issued a CCUS report in 2020, which presented a CCUS cost projection under the Sustainable Development Scenario (SDS). The scenario featured elevated climate commitments one-notch below the ambitious Net Zero Emissions (NZE) 2050 scenario.<sup>103</sup> Under the scenario, cost of CO<sub>2</sub> capture in coal power is projected to decline from ~US\$65/tCO<sub>2</sub> in 2020 to US\$40/tCO<sub>2</sub> by 2070, assuming a rapid uptake of CCUS. At a potential price of US\$40/tCO<sub>2</sub> in 2070 for capture, compounded with additional costs for transportation and storage, the price range of CCUS application will very likely be way outside what emerging markets in SEA could afford in the next couple of decades.

Projecting the future cost and growth rate of developing technologies is inherently full of uncertainty, just as past forecasts on solar PV growth has demonstrated.<sup>104</sup> It is nevertheless an essential exercise to help understand the potential pathways. Notably, the ‘learning rate’ exhibited by the IEA projection is substantially lower than the path of solar PV. This would likely be related to the slower CCUS adoption due to the high cost and custom-fitted nature of CCUS applications.<sup>105</sup>

**Figure 14: The Different Scale of CCUS**

Source: Petra Nova, Texas Tribune.

Whereas PV can be scaled up through mass production with incremental improvements at relatively low costs. Lessons from CCUS will likely need to be accumulated one plant at a time, each with considerable associated costs and time.

With the high cost of failure, the design-build-prove cycle of CCUS will potentially operate on a different time scale, and the path for scaling-up CCUS will likely play out differently. It is arguably easier to learn from and incrementally improve a US\$3-4m wind turbine than a demonstration project costing hundreds of millions of dollars.

In order to help accelerate the cost decline, some technology proponents have been developing ‘modularized’ carbon capture plant design with 0.002 to 0.2 MTPA capacity. The standardization of designs is touted to reduce costs more effectively

<sup>103</sup> Readers are encouraged to be familiar with IEA scenarios, including the Announced Policy Scenarios (APS) and Stated Policy Scenarios (STEPS) International Energy Agency. [Understanding World Energy Outlook scenarios](#). 2021.

<sup>104</sup> PV-Magazine. [IEA versus the reality of solar PV](#). 20 November 2018

<sup>105</sup> CCUS design will typically need to be customized to the planned facility, this is in contrast to the mass-production model associated with other technologies such as PV.

and allow it to be deployed by many scales. A plausible concept of which results remain to be seen. Nevertheless, the applications of CCUS in tight-space locations, such as offshore gas production platforms, have also been performed in a somewhat similar fashion for decades.<sup>106</sup> It is also noteworthy that these modularized CCUS technology potential applications will likely lean more towards industrial applications and less applicable for power generation plants with multi-million tonnes of annual CO<sub>2</sub> emissions.

#### **Claims of cost projections and decline.**

With limited project development in power generation and CCUS Petra Nova's closure, an assessment of the actual cost of CCUS will likely remain ambiguous for the near future. In 2021, an IEEFA report highlighted that the often cited claims of a continual cost decline trend of CCUS could muddle understanding.<sup>107</sup>

In the report, IEEFA emphasized that 'the only potentially accurate capture costs shown in Figure 15 are the US\$60 to \$65 cost for Petra Nova and the US\$100-plus cost for Boundary Dam. We say "potentially actual" because no actual operating costs have been released for Petra Nova or Boundary Dam 3. All the other carbon capture costs shown in the figure are merely estimates for past projects that have not been built, or for future projects that have not been built, and may never be built. It is wise to remain prudent in assessing the actual costs and projected costs of CCUS.

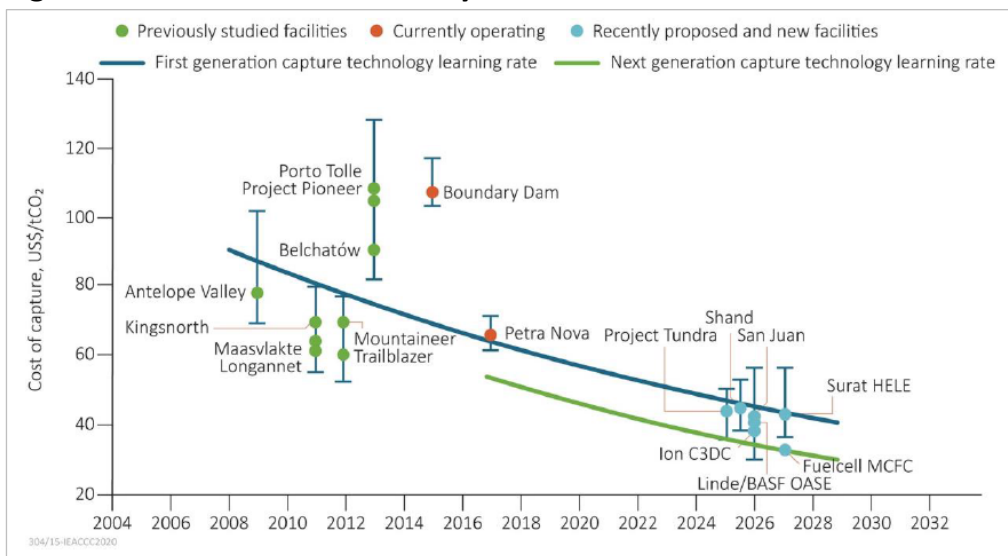

**With the high cost of failure, the path for scaling-up CCUS will likely play out differently. It is arguably easier to learn from and incrementally improve a US\$3-4m wind turbine than a demonstration project costing hundreds of millions of dollars.**

## CCUS Leadership in Asia

With the technology-intensive nature of CCUS, several countries could provide reference points for the CCUS potential in Asia: China, Japan, and South Korea. All three countries have a long history of technology leadership and energy investments in the region. Their experiences with CCUS can provide a glimpse into the future path of CCUS in SEA.

### China

China has been slow in its development and uptake of CCUS. Most of China's existing CCUS is considered small-scale, with the estimated aggregated capacity ranging from 2 to 4 MTPA CO<sub>2</sub>, spread over dozens of small-scale facilities.<sup>108</sup> Compare this with the US' Shute Creek treating plant's 7 MTPA CO<sub>2</sub> capacity (in a single plant). It is clear that China has a lot of catching up to do.

Although most are still in early stages, potential projects are being proposed and prepared. Notable project plans, such as the CNOOC CCUS in the South China Sea (1.5 MTPA CO<sub>2</sub>) and the recently established Sinopec's Jiangsu, CCUS (0.2 MTPA CO<sub>2</sub>) have been primarily led by Chinese oil and gas companies. It is estimated that more than 70% of the national capacity is operated by Sinopec, CNPC and the CNOOC Group.<sup>109</sup>

<sup>108</sup> Argus. [Carbon storage, H2 key to China net-zero goal: Shell](#). 18 January 2022.

IHSMARKIT. [China inches forward on CCUS deployment with Sinopec pilot project](#). 6 January 2022.

South China Morning Post. [Climate change: China's plant to double carbon capture capacity by 2025 hinges on securing funding for projects](#). 14 June 2021.

<sup>109</sup> Reuters. [China's CNOOC launches first offshore carbon capture project](#). 30 August 2021.

In terms of innovations, it is worth noting that between 2020-21, 81% of patents in CCUS filed with the World Intellectual Property Organization (WIPO) were of Chinese origin.<sup>110</sup>

While the development of CCUS and China remains to be seen, it will likely not escape the basic tenet of the CCUS discussion – that attaching a high price to carbon emissions is necessary. A recent report from Shell China suggested that a carbon price of US\$47/tCO<sub>2</sub> by 2030, and US\$205 by 2060, will likely be required to achieve China's 2060 carbon-neutral target, which includes the widespread adoption of CCUS.<sup>111</sup> With China's Emission Trading Scheme's (ETS) carbon price projected to hover around US\$10/tCO<sub>2</sub> in 2022, there is still some catching up to do.<sup>112</sup>

## Japan

With Mitsubishi Heavy Industry (MHI) already playing a prominent role in certain CCUS applications, Japan will likely want to pursue a leading role in CCUS development in Asia. This trend has been displayed in Japan's leadership in a number of CCUS feasibility studies, and in the establishment of the Asia CCUS Network Forum, with member states from Southeast Asia, US, Australia, and India.<sup>113</sup>

While Japan has supported many CCUS initiatives, the plan for CCUS is somewhat less ambitious at home. This is potentially due to the conservative approach in assessing storage in the earthquake-prone region. A long-term CCS trial of 0.2 MTPA capacity has been completed between 2016 and 2019, with further demonstrations planned in power generation applications.

Japan's CCUS goal has likely been spurred by both its significant coal and gas power fleet, as well as an anticipation of the future potential of the hydrogen/ammonia value chain. The country, which will likely leverage its experience in the power and LNG sectors, has also shown particular interest in 'carbon recycling'. This is the utilization of captured carbon, with the ambition to secure 30% of the global market by 2050.<sup>114</sup>

<sup>114</sup> Japan Ministry of Economy, Trade, and Industry. [Japan Green Growth Strategy](#). 2021.

## South Korea

South Korea has outlined plans to invest in CCUS, both domestically and overseas.<sup>115</sup>

Early plans have been reported that South Korea is exploring a CCUS collaboration with Malaysia, specifically involving its steel giant POSCO and Petronas.

In 2021, South Korea's utility KEPCO and its six subsidiaries announced an exit from coal by 2050. The company announced plans to commercialize CCUS technology for 500MW of coal power and 150MW of gas power by 2030.<sup>116</sup> The company's current CCUS utilization is largely limited to small-scale pilot installations.<sup>117</sup>

Traditionally, the export of technologies and concessionary financing from these three countries has been vital in promoting various technology applications in SEA. As it stands, all of them are significantly behind in terms of CCUS applications compared to establishments in North America. Despite the growing need to implement CCUS to mitigate emissions, none have yet to develop a commercially viable model for widespread CCUS adoption.

It is also notable that these three countries have varying degrees of CCUS drivers, with South Korea exhibiting the most mature carbon pricing system. Meanwhile, Japan has some form of regulatory emissions control, but the country's carbon pricing remains paltry at best, with a carbon tax of around US\$3/tCO<sub>2</sub>e. This is despite actively promoting CCUS in SEA.

With announced government commitments from all three countries to support net zero targets, the CCUS development in these countries will likely shape the outlook of Asia. This is particularly salient with the US (which is home to most of CCUS' current fleet) rapidly departing from coal. Along with this, so will their focus on coal power CCUS, a dominant part of SEA power mix.<sup>118</sup>

Stakeholders in SEA should remain cautious of CCUS' progress in these countries, while also paying attention to

**With the US – home for most of the current CCUS fleet – rapidly departing from coal, so will their focus on coal power CCUS, a dominant part of SEA power mix.**

specific policies and public financing support that is attached to such developments.

### *Where Would the Path of CCUS in South East Asia Lead?*

As a concluding remark, IEEFA believes that the establishment and growth of CCUS in the South East Asian market within the next several decades, will likely be limited around gas processing and some stand-alone industrial applications. This could be supported by concessionary financing or bilateral initiatives.

The ongoing CCUS plans are evidence that the region is playing catch up to mature CCUS technologies in the gas sector, potentially anticipating possible changes in market attitudes towards CO<sub>2</sub>-rich gas in the future.

Host countries would be well-served to understand the implications of internal carbon pricing for investing companies in finding a fair share of cost allocations, if and when, CCUS is deployed.

IEEFA believes that the widespread adoption of CCUS in SEA's power sector remains highly unlikely within the next several decades. The development of affordable coal power CCUS remains elusive and potentially even more so for gas power. Even at the US\$40/tCO<sub>2</sub> cost of capture, the effective total cost of US\$50 to 60/tCO<sub>2</sub>, inclusive of transport and storage, will be beyond the reach for most countries in the region.

In assessing the full costs of CCUS in SEA against the alternatives, a multitude of factors will need to be considered, including the predominance of subcritical coal plants, and the costs of flue gas pre-treatment facilities. Further, costs of CO<sub>2</sub> *avoided* should be the main focus to avoid neglecting the emissions resulting from the energy intensive CCUS process.

The establishment of CCUS hubs in locations such as Singapore remains a possibility, given the concentrated industrial base and less cost-sensitive, export-based nature of the market. As mentioned previously, deeper coverage of the potential of CCUS-based products, such as hydrogen and ammonia, is beyond the scope of this paper, but will likely be part of future IEEFA publications.

CCUS will undoubtedly remain key for some hard-to-abate sectors. It is nevertheless important for stakeholders to note that many of the existing, and upcoming, CCUS projects in the US and EU lean heavily on public funding support, which may not be readily available in SEA countries.

The recent IPCC report, issued in 2022, has outlined the challenging costs of CCUS applications in the near future. With limited resources, CCUS is ultimately a question of priorities, as the costs will eventually land somewhere. It is also pertinent to ask whether the CCUS projects planned in the region match the 'intended CCUS' for each respective country's commitment towards their decarbonization goals.

SEA countries can use CCUS as a stepping stone to 'learn the ropes' of the technology and to anticipate future developments of carbon-capture based export products and other technologies. However, it should not distract from the adoption of other

lower-cost options in renewable energy and grid integrations. This should remain at the centre of SEA's attention toward decarbonization.

It is possible that the cost of CCUS in power generation will decline substantially over the next two decades, but historical experience and the factors outlined throughout this report suggest its likelihood remains questionable, especially for adoption in cost-sensitive markets. The CCUS train may eventually arrive, but before it does, it will likely need to make a lot of stops before reaching the South East Asian shores.

## Appendix A

### Select Gas Processing CCUS Projects

Facility	Reservoir-associated CO <sub>2</sub> Content	Plant Capacity Million Tonne Per Annum (MTPA) Start Operation	CO <sub>2</sub> End Use	Realization & Remarks
<b>Shute Creek Treating Facility, LaBarge, US</b> ExxonMobil	~ 65% <sup>119</sup>	7 MTPA CO <sub>2</sub> 1986, extended in 2010 <sup>120</sup>	EOR	Plan for additional 1MTPA capacity has been reported in 2021. <sup>121</sup> ExxonMobil proprietary technology controlled freeze zone was patented in 1986 and demonstrated in LaBarge in 2010 LaBarge facility is also one of the largest helium recovery plants in the world, supplying more than 20% of global capacity.
<b>Century Plant</b> Occidental Petroleum, SandRidge	Up to 65% <sup>122</sup>	5 MTPA CO <sub>2</sub> in use <sup>123</sup> 2010	EOR	Facility reported built with 8+ MTPA capacity
<b>Santos basin, Brazil</b> Petrobras	8 – 20% CO <sub>2</sub> <sup>124</sup>	4.6 MTPA CO <sub>2</sub> 2013 (Petrobras reported 2008)	EOR	Injected 4.6mT CO <sub>2</sub> in 2019. 14.4 miTonne cumulative volume between 2008 and 2019, expected cumulative volume of 40mT by 2025 <sup>125</sup>
<b>LNG - Gorgon, Australia</b> Chevron LNG Operation : 15.6 MTPA LNG <sup>126</sup> Chevron (47.3%), ExxonMobil (25%), Shell (25%), Osaka Gas (1.25%), Tokyo Gas (1%), JERA (0.417%)	14% <sup>127</sup>	4 MTPA CO <sub>2</sub> <sup>128</sup> 2019	Storage	Underperformed its self-set targets for the first five years by around about 50%. Gorgon has recently agreed to acquire and surrender credible greenhouse gas (GHG) offsets recognised by the Western Australian Government to offset its target. The shortfall amounts 5.23 million tonnes of CO <sub>2</sub> with cost estimates vary from US\$100 million to US\$184 million. A report which was made public by the Australian government in 2022 further outlined that CCS plant has injected 2.26m tonnes of CO <sub>2</sub> over a one-year period, significantly below its targeted 4 MTPA capacity. <sup>129</sup>

Advanced Development	Delay reported, see remarks	<b>San Juan Generating station</b>	US	2023	Coal Subcritical.	Retrofit	1973, 1982	940MW 847MW (nett)	5.8 - 6.5	EOR + Storage	<b>Amine based KM CDR (Mitsubishi Heavy Industries)</b> 2021 Enchant presentation suggests MHI involvement is being finalized with 95% warranted carbon removal.	<a href="#">Enchant Energy</a>	<b>Delay announced July 2021.</b> Enchant aim to obtain 1bn\$ low-interest from DOE for the 1.6bn project. 1.6bn for CCUS and pipeline. Announced in 2019, initially planned for 2023, now scheduled for 2024. Funding difficulties, IEEFA foresee timing potential delay 2026-28. Plan to sell CO2 for EOR and 45Q, noting that the unit will need to operate at 85% capacity compared to 64% historical record. IEEFA estimate 2.2-3.3 bn investment is required. Planned to be connected to Kinder Morgan Cortez CO2 pipeline (20 mile away).  The project received \$21M of US Government grants (DOE and then DOE) to support storage feasibility studies (FOA 1999 in addition to FOA 2058 associated to capture process FEED studies)
Advanced Development	FDI planned for 2021	<b>Coyote Clean Power project</b>	US	2025	Gas	Newbuild, new tech	N/A	280MW each	0.86	Under evaluation	<b>Oxy fuel combustion - Allam Cycle (NET Power)</b> Combusting gas with pure oxygen, the use of supercritical CO2 as heat exchange instead of water. Technology trialed on 25MW (2018) plant in La Porte, Texas	<a href="#">Coyote Energy (Rivers, Net Power)</a>	FDI planned in 2022. Implementation of new technology (NET power) with semi closed loop system. Aim to access 45Q. Expecting 500MW+ for each plant, with final utilization/storage under evaluation (BBG, April 2021)  In 2012, NET Power received a GIP 4.9M grant from UK Department of Energy and Climate Change for the development of the technology.
Advanced Development	Delay reported, see remarks	<b>Project Tundra</b>	US	2025-6	Coal	Retrofit	1970, 1977	450MW Unit 2	3.1-3.6	EOR + Storage	<b>Econamine FG Plus Amine-based (Fluor Corp)</b>	<a href="#">Minnesota power cooperative</a>	<b>Delay reported Oct 2021, engineering contractor pulled out in March 2021.</b> Seeking 700MS DOE loan guarantee (S&P Global) 1bn\$ investment required, to tap into Milton R. Young station (250 + 455 MW). Project Tundra is reported for Young Unit 2 (up to 90% emission). In advanced stage, construction may commence in 2023. The aim is to proceed before 2023 deadline of 45Q.  Minnesota received 9.8MS grant from DOE in 2019 for front end engineering, total of 43MS.
Advanced Development	FEED expected completion 2023	<b>Humber Zero VPI Immingham power plant</b>	UK	2027	Gas turbine	Retrofit	2004, expanded 2009	1.3 GW CHP (720MW in 2004, 1.6GW in 2009)		Storage	<b>Amine based</b> Limited information	<a href="#">Vitol, VPI Immingham, Phillips 66</a>	Power plant provide steam and power to Phillips 66 Humber refinery and Prax Group's Lindsey refinery (25% of UK capacity). Secured 11.5 GGBP in funding in March 2021 from innovative UK's industrial strategy challenge fund to develop technology. A combined project between CCS alongside blue and green H2. Target to remove BMTPA CO2 by 2030.
Advanced Development	FEED ongoing (scheduled complete 2021)	<b>Mustang station of golden spread electric cooperative</b>	US	mid 2020s	Gas Turbine	Retrofit	2000 later OGC 2006/7/13	430MW (UT reported CC capacity)	1-1.5	Under evaluation	<b>PZAS Piperazine Advanced Stripper (Univ of Texas)</b> Developed with US DOE. Initial research since 2000, pilot for 12% CO2 coal plant at UT, NCCC (2010-18), for 4% CO2 NGCC UT NCCC (2016-19)	Golden Spread Electric Cooperative	DOE reported FEED study in 2010 with University of Texas. 4.1 MS DOE funding scheduled 2019-2021.
Advanced Development	Limited information. FEED ongoing (scheduled complete 2022)	<b>Plant Daniel</b>	US	mid 2020s	Gas	Retrofit	2001	Minimum 375MW	1.6-1.8	Storage	<b>Advanced aqueous amine solvent (Linde-BASF)</b>	Mississippi Power	DOE reported awarding 5.6MS for FEED scheduled to complete in 2022
Advanced Development	Limited information. FEED ongoing (scheduled complete 2022)	<b>Gerald gentlemen station</b>	US	mid 2020s	Coal	Retrofit	1982	300 MWe slipstream (up to 700MW (ION))	4.3	Under evaluation	<b>Advanced low-aqueous solvent (ION Engineering).</b> Lab pilot in 2010 (0.01Mw 54M) - 2015 National CC Center (0.5MWe 510M) - 2016/7 Mongstad (12MW 515M) Norway. Reported to be more efficient in 12MWe trial in Mongstad Norway (2016-17), with 30% reduction in parasitic load	Nebraska Public Power District	DOE funding for study reported 2.8MS (DOE-NETI) with Phase II 5.6MS reported by NPPD FEED initiated in 2018. Timeline reported by ION suggest FEED will be completed by 2022, with construction in 2023 prior to 45Q deadline
Advanced Development	Limited information. FEED ongoing (scheduled complete 2022)	<b>Prairies state generating station</b>	US	mid 2020s	Coal Supercritical	Retrofit	2012	816MW (Unit 2)	5 to 6	Storage	<b>Amine based Advanced KM CDR (Mitsubishi Heavy Industries)</b> Plan to apply KS-21 solvent with advantage over KS-1 (Petra Nova). R&D began in 1990. KM CDR (Kamati Mitsubishi CO2 Recovery Process) was developed in 1994, and has been applied globally, including the earlier version (KS-1) in Petra Nova (2016). Water supply highlighted as a key issue.	Prairie state Energy Campus	DOE funding reported 14MS for a FEED study scheduled 2019-2022. The largest coal plant built in the US in 30 years, mine-mouth power plant. IEEFA has extensive coverage of the development of this power plant and its coal supply chain.
Advanced Development	FEED reported to be completed. FDI planned for 2021	<b>Bridgeport Energy Moonie</b>	Australia	2023	Coal Supercritical	Retrofit	2003	Tapping into 850MW power plant	0.12 to 2	EOR	<b>China Huaneng's CO2 technology (limited info).</b> Partner with China Huaneng Group (CHG, shareholder in Millerman power station). MoU with CTCSo signed in April 2021. In 2009 Huaneng reported the costs was still expensive at ~40\$/t (Reuters). Note that Huaneng is also developing CCS for IGCC application	CTSCo (Glencore)	Plan to tap into the Millerman CFPP (850MW total, InterGen, Commissioned 2003). Note that the scale of the capture is very small compared to the 850MW capacity. Received EP100 GHG exploration permit in 2019 to assess storage viability. Glencore reported capacity of 0.11 MTPA. Liquefied CO2 is planned to be trucked 100km away (ABC) Received AUS\$34 federal funding for CCUS reported in 2018 (ABC). Received funding from COAL21 fund (BETA) in 2014. Project cost expected AS 210 (CTSCo fact sheet)
